# ARCH models for Value at Risk forecasting in Latin American stock and Forex markets

Alejandro Cermeño

Pontificia Universidad Católica del Perú

October 19, 2021

### Estructura

- Introduction
- 2 Literature Review
- Methodology
- Empirical evidence
  - Data
  - Results
- 5 Conclusions (for stock markets)
- 6 Agenda

### Literature Review

Stylized facts of financial returns: Franses and van Dijk (2000), Engle (2004) and Teräsvirta (2009)

- Clustering of extreme returns
- Non normality in distribution
- Leverage effect: high volatility after extreme negative returns
- ullet Long memory in  $r_t^\delta$  or other transformations

### Literature Review

- Engle (1982) proposes the ARCH model and Bollerslev (1986) generalizes it to GARCH.
- Arch-type models have been widely developed. Key references are Glosten el at. (1993), Ding et al. (1993) and Baillie et al. (1996).
- Volatility as a key input in Value at Risk: Angelidis et al. (2004) for the major stock indices, Fan et al. (2008) for crude oil price, Liu and Hung (2010) for S&P 100, Brooks and Persand (2003), Ardia and Hoogerheide (2014), among others.

## Methodology

A complete ARCH model is divided into three components:

- a mean model: zero, constant, AR(1)
- a volatility process: ARCH, GARCH, GJR, FIGARCH, APARCH.
- ullet a distribution for the standardized residuals: Normal,  $\mathcal{S}$ -Student, Skeweed, and generalized error distribution (GED).

# Methodology ARCH models

The ARCH model of Engle (1982)

$$\sigma_t^2 = \omega + \sum_{\rho=1}^P \alpha_\rho \epsilon_{t-P}^2 \tag{1}$$

The GARCH model of Bollerslev (1986)

$$\sigma_t^2 = \omega + \sum_{i=1}^q \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^p \beta_j \sigma_{t-j}^2$$
 (2)

The GJR (1993) model

$$\sigma_t^2 = \omega + \sum_{i=1}^q \alpha_i \varepsilon_{t-i}^2 + \sum_{i=1}^q \gamma_i I_{[\varepsilon_{t-i} < 0]} \varepsilon_{t-i}^2 + \sum_{j=1}^p \beta_j \sigma_{t-j}^2$$
 (3)

# Methodology ARCH models

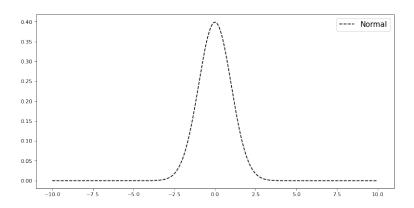

The FIGARCH of Baillie et al. (1986)

$$\sigma_t^2 = \omega + \left[1 - \beta L - \phi L (1 - L)^d\right] \varepsilon_t^2 + \beta \sigma_{t-1}^2 \tag{4}$$

The APARCH of Ding et al. (1993)

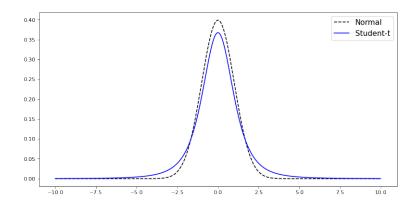

$$\sigma_t^{\delta} = \omega + \sum_{i=1}^{q} \alpha_i \left( |\varepsilon_{t-i}| - \gamma_i I_{[o \ge i]} \varepsilon_{t-i} \right)^{\delta} + \sum_{i=1}^{p} \beta_i \sigma_{t-i}^{\delta}$$
 (5)

# Methodology Distributions

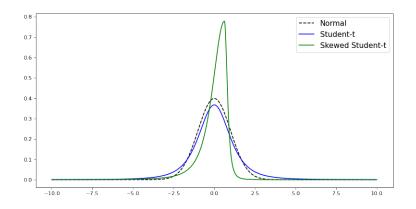

## ${\sf Methodology}$

#### Distributions

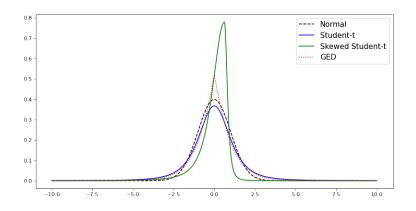

# ${\sf Methodology}$

#### Distributions

# ${\sf Methodology}$

#### Distributions

### Value at Risk and backtest

$$\widehat{VaR}_{t+1}^{\alpha} = -\hat{\mu}_{t+1} - \widehat{\sigma}_{t+1} q_{\alpha} \tag{6}$$

### backtest procedures:

- Unconditional coverage (UC) test of Kupiec (1995)
- Conditional Coverage (CC) test of Christoffersen (1998)
- Dynamic quantile (DQ) test of Engle and Manganelli (2004).

### Empirical Evidence: Data

- Countries: Argentina, Brazil, Chile, Colombia, Mexico and Peru
- Markets: stocks and Forex
- Frecuency: daily
- Source: Bloomberg Financial Data
- Returns are calculated as  $y_t = 100 * [\log{(p_t)} \log{(p_{t-1})}]$

(b) Forex Market Returns

## Conclusions (for stock markets)

- In general, FIGARCH volatility process and leptokurtic distributions are able to produce better one-step-ahead VaR forecasts
- The models that best fit the full series in-sample are not necessarily the ones that obtain the most accurate VaR forecasts out-of-sample
- The models producing the most accurate forecasts vary by market and country.

### Agenda'

- Obtain the results also for the Forex market
- Compare the results for the stock market and the Forex market.
